A paper with a *very* long extended version full of proofs

# Some Historical Context

---

*Dynamically Typed Call-by-push-value.* Our interpretation of the dynamic types in CBPV suggests a design for a Scheme-like language with a value and computation distinction. This may be of interest for designing an extension of Typed Racket that efficiently supports CBN or a Scheme-like language with codata types. While the definition of the dynamic computation type by a lazy product may look strange, we argue that it is no stranger than the use of its dual, the sum type, in the definition of the dynamic value type. That is, in a truly dynamically typed language, we would not think of the dynamic type as being built out of some sum type construction, but rather that it

---

is the *union* of all of the ground value types, and the union happens to be a *disjoint* union and so we can model it as a sum type. In the dual, we don't think of the computation dynamic type as a *product*, but instead as the *intersection* of the ground computation types. Thinking of the type as unfolding:

$$\underline{\dot{c}} = \underline{F}\underline{\dot{c}} \wedge (? \rightarrow \underline{F}?) \wedge (? \rightarrow ? \rightarrow \underline{F}?) \wedge \dots$$

This says that a dynamically typed computation is one that can be invoked with any finite number of arguments on the stack, a fairly accurate model of implementations of Scheme that pass multiple arguments on the stack.

## Call-By-Push-Value: A Subsuming Paradigm (extended abstract)

Paul Blain Levy\*

Department of Computer Science, Queen Mary and Westfield College  
LONDON E1 4NS [pb1@dcs.qmw.ac.uk](mailto:pb1@dcs.qmw.ac.uk)

**Abstract.** Call-by-push-value is a new paradigm that subsumes the call-by-name and call-by-value paradigms, in the following sense: both operational and denotational semantics for those paradigms can be seen as arising, via translations that we will provide, from similar semantics for call-by-push-value.

To explain call-by-push-value, we first discuss general operational ideas, especially the distinction between values and computations, using the principle that “a value is, a computation does”. Using an example program, we see that the lambda-calculus primitives can be understood as push/pop commands for an operand-stack.

We provide operational and denotational semantics for a range of computational effects and show their agreement. We hence obtain semantics for call-by-name and call-by-value, of which some are familiar, some are new and some were known but previously appeared mysterious.

In our paper, we heavily  
used the CBPV calculus.

It simplified the semantics  
and proofs.

**But what would a programming  
language directly based on  
CBPV look like?**

# A language-design experiment

---

*What if Scheme were based on CBPV?*

# Minimalist Philosophy

---

**Scheme** 🤝 **CBPV**

Use composition to build complex features  
**from a small core.**

# CBPV separates values from computations

---

value types  $A ::= UB \mid \sum_{i \in I} A_i \mid 1 \mid A \times A$

computation types  $\underline{B} ::= FA \mid \prod_{i \in I} \underline{B}_i \mid A \rightarrow \underline{B}$

**Value types classify data.**

**Computation types classify the stacks that programs run against.**

*Source: Paul Blain Levy, Adjunction Semantics for Call-By-Push-Value (2004), slide 13.*

# Application pushes; lambda pops

---

$$\frac{V' M}{M} \quad \frac{K}{V :: K} \quad \rightsquigarrow$$

$$\frac{\lambda x. N}{N[V/x]} \quad \frac{V :: K}{K} \quad \rightsquigarrow$$

So  $V'$  means **push**  $V$  and  $\lambda x$  means **pop**  $x$ .

A computation in  $A \rightarrow \underline{B}$  pops a value in  $A$ , then behaves in  $\underline{B}$ .

*Source: Paul Blain Levy, Adjunction Semantics for Call-By-Push-Value (2004), slide 27.*

# CBV Function Decomposition

---

A CBV type translates into a value type.

$$A \rightarrow B \mapsto U(A \rightarrow FB)$$

# CBV Function Decomposition

---

A CBV type translates into a value type.

$$A \rightarrow B \mapsto U(A \rightarrow FB)$$

- U** Closure: suspended code.
- A**  $\rightarrow$  Argument: a value supplied on the stack.
- F B** Return continuation: what consumes the result.

# Scheme Minimalism

---

A tiny set of primitive ingredients:

atoms + cons cells + closures

**More complex data (lists, trees) built up  
from just a single binary data constructor**

# Scheme Minimalism?

---

Closures come with a richer argument protocol:

`(lambda (x y) ...)`

fixed arity

`(lambda (x y . rest) ...)`

collect extras as a list

`(case-lambda [(x) ...] [(x y) ...])`

dispatch on arity

`(apply f args)`

supply arguments from a list

**Compound, arbitrary size constructs are baked into the core of procedures.**

# Fiddle: A CBPV Scheme

---

Treat the stack the way Scheme treats data.

|        | BASE CASE     | EXTENSION | INSPECTION         |
|--------|---------------|-----------|--------------------|
| VALUES | atomic data   | cons      | car/cdr/cons?/nil? |
| STACKS | continuations | argument  | case-lambda        |

**pushing an argument is the cons of the stack.**
